Development Process AutoCAD is a commercial product developed using an iterative development process, meaning changes are made to a program as a whole, rather than individually as they are developed. According to Autodesk, they can release a new version of AutoCAD in as little as six weeks. The first public use of AutoCAD was by Softimage in 1982 for their Line-drawing and cutting software, Nexti. It was an independent product, with Softimage president Alan Shultz explaining in an interview, "AutoCAD was started as a hardcopy system for the 3D design of objects. But most of the people who would be using the software were comfortable with

paper, and didn't want to have to get up and print it out every time they wanted to see their model. So we made a choice to write the program so that you could see the results on the screen." The idea for AutoCAD was born in 1978 when Softimage (which was developing graphics software for computers with no built-in graphics hardware) released a product that was essentially a paper-based successor to 2D drafting software that had been around for many years. It contained all the traditional paper-based drafting tools, but they were augmented with some graphical features. Alan Shultz recalled, "One of the problems with a previous product we released was that it only worked with certain printers. And for the purpose of that product, it was fine, but it was not intended to be a general-purpose computer

graphics program. It was a CAD program. It worked great for it, but if you were trying to use it to produce a drawing that could be used in multiple places, it was not a good solution." After two years of development, AutoCAD was ready to enter the market. Softimage was purchased by Unisys in 1982, who renamed the product Line-builder. (Unisys also released their own CAD program, named the Unisys CAD Editor.) "I like to imagine that my group, in a separate building, decided to get together and come up with a new programming language, in the same way that every programmer would do. And it's just the way that it was," said Alan Shultz. "They would sit around a table and argue for a while about what programming language they should use, and at some point someone

would say, 'Well, I don't know. Let's just write a program in English.' And then they would try to

Bronchial neuroendocrine tumours (NETs) are rare lesions of the lung. They are usually seen in patients with lung cancer and may be associated with other tumours, such as gastrointestinal carcinoids. As the prognosis of patients with NET is very good, the most effective treatment is radical surgical resection. Surgical removal can be achieved by thoracotomy or thoracoscopy. In the latter, the diameter of the lesion is usually much larger than that of the lesion that can be removed safely by the traditional

thoracotomy approach. The operative procedure is challenging, as it requires thorough lung mobilization. The aim of the present study is to assess the feasibility and the technical aspects of video-assisted lobectomy of these lesions. We present a patient with a small (3 cm) endobronchial NET who underwent video-assisted lobectomy with systematic lymph-node dissection (8 stations). The approach was thoracoscopic. The postoperative course was uneventful. This video represents a case of endobronchial NET that was resected successfully with video-assisted thoracoscopic surgery (VATS). The procedure was performed through a single-port incision under general anaesthesia. The patient was discharged on the first postoperative day, and on the 6th day a

chest computed tomography (CT) scan showed the absence of residual disease. VATS should be considered in the surgical management of selected patients with bronchial NETs. The tumour size, localization and accessibility should be considered to define the most suitable approach for each patient. When performed successfully, this approach should be considered a valid option for the treatment of selected patients with bronchial a1d647c40b

The aim of the network, the first part of which will be delivered by 2010, is to avoid the need to build a new main line every time a private firm decides to add to or replace capacity on a rail network. The network will comprise 15,000km of track, and the majority of it will be owned by the private sector but run by Network Rail, a joint venture between the private firms of

infrastructure and rail freight companies.
